
Agentic Agile Product Development

August 2026

By Ari Koinuma

Everyone does agile, but the point is often missed

You want to
timebox releases

To reduce the risk
of over-investing in
features that don't
lead to results

You want to
listen to feedback

Otherwise you won't
know your product is
achieving the
intended results

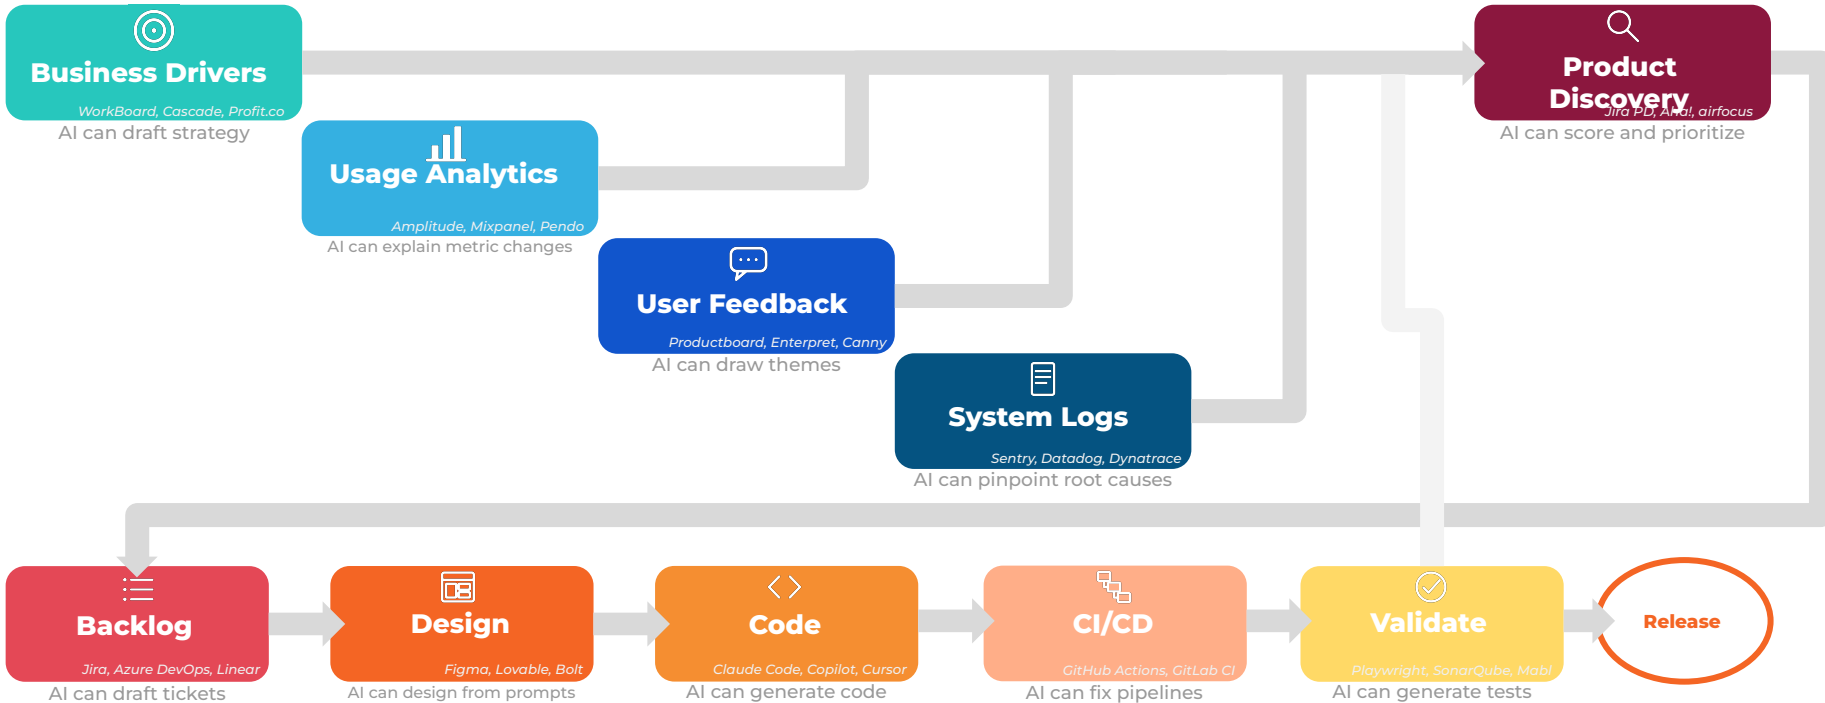

You want to
continuously reprioritize

So that high-value
activities are always
executed first

But there is too much to process manually

Agentic Agile Product Development

Finally, AI can help process all the data and speed up tasks for effective agile delivery.

Business Drivers

AI can draft strategy

Business drivers rarely arrive as clean data. They're buried in a strategy deck, scattered meeting notes, or a spreadsheet of goals split across teams. AI can read through that material and turn it into an actual working draft: structured objectives, current status, and which ones are falling behind.

That drafted structure carries into the update work too, turning meeting notes into the review-ready summary a leadership team would otherwise write from scratch. Objective tracking can run continuously as well, with some platforms flagging drift the moment it happens rather than waiting for the next check-in.

Leading tools: WorkBoard, Cascade, Profit.co*

Usage Analytics

AI can explain metric changes

Dashboards pile up numbers fast, but a chart alone rarely explains why a metric moved. AI can dig into the underlying activity data and put that explanation into plain language: which segment shifted, what changed right before it, and how significant the move actually is.

That explanation used to take an afternoon of manual queries to piece together. Now it can surface automatically, with some platforms watching metrics around the clock and flagging anomalies the moment they appear.

Leading tools: Amplitude, Mixpanel, Pendo*

User Feedback

AI can draw themes

Feedback lands scattered across reviews, tickets, calls, and surveys, too much volume for anyone to read line by line. AI can draw the throughline out of that noise, surfacing the themes that actually repeat instead of just the loudest single complaint.

Those themes can come ranked too, by how often they show up and how urgent they are, so the pattern is visible at a glance. Some platforms keep drawing that picture continuously, updating as new feedback lands rather than refreshing it once a quarter.

Leading tools: Productboard, Enterpret, Canny*

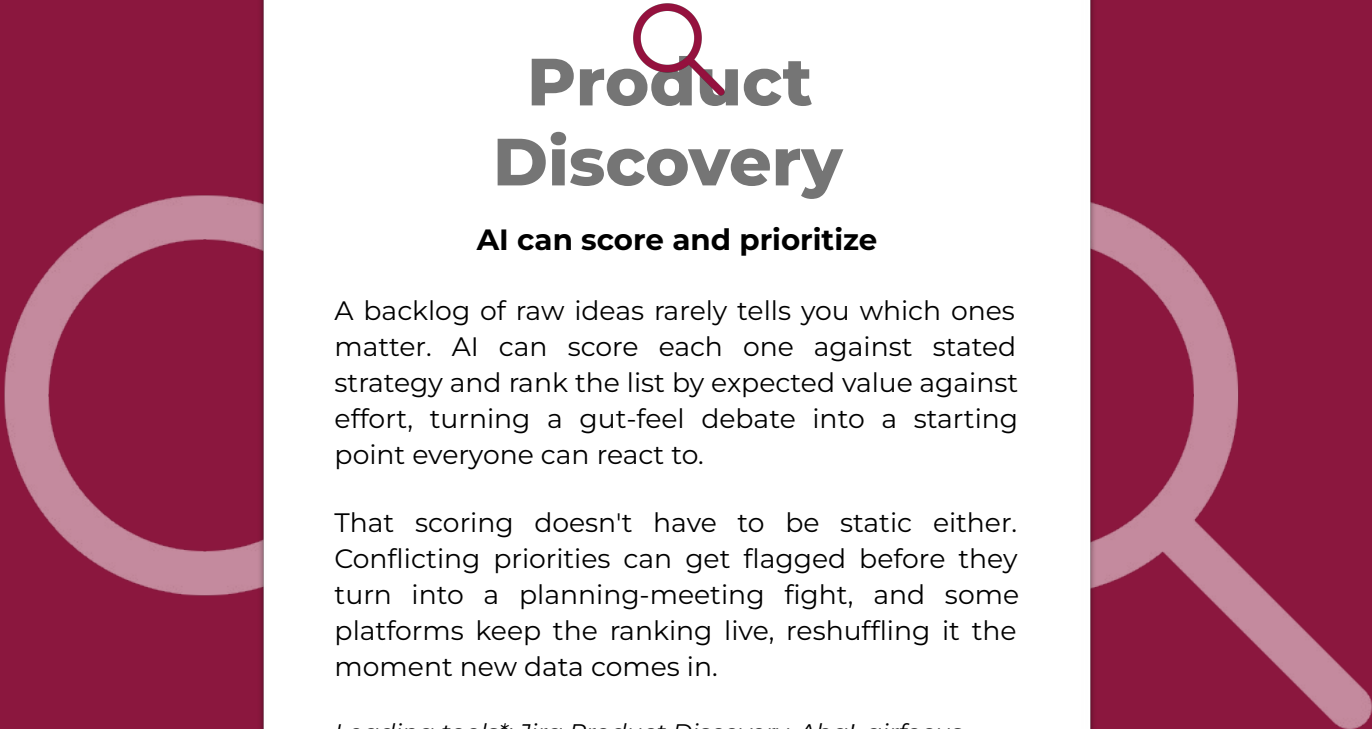

System Logs

AI can pinpoint root causes

A single outage can throw off thousands of log lines and a dozen false leads. AI can cut through that noise and pinpoint the actual cause, correlating logs, traces, and the code change that likely triggered it.

Finding the cause is only half the job, though. Once it's pinpointed, AI can draft the fix too, and some platforms go as far as opening a ready-to-review pull request the moment they've diagnosed the failure.

Leading tools: Sentry, Datadog, Dynatrace*

Product Discovery

AI can score and prioritize

A backlog of raw ideas rarely tells you which ones matter. AI can score each one against stated strategy and rank the list by expected value against effort, turning a gut-feel debate into a starting point everyone can react to.

That scoring doesn't have to be static either. Conflicting priorities can get flagged before they turn into a planning-meeting fight, and some platforms keep the ranking live, reshuffling it the moment new data comes in.

Leading tools: Jira Product Discovery, Aha!, airfocus*

Backlog

AI can draft tickets

Turning a decision into a well-formed ticket is repetitive: writing the description, acceptance criteria, and estimate every time. AI can draft all three from a short plain-language description, consistently rather than however each writer happens to phrase it.

That same drafting extends further up the chain. A large epic can be broken into right-sized stories automatically, with anything not sprint-ready flagged before it derails planning. Some platforms will even draft the full sprint for a human to review.

Leading tools: Jira, Azure DevOps, Linear*

Design

AI can design from prompts

A blank canvas is often the slowest part of design. Describe the screen or paste a rough sketch, and AI can turn that prompt into a working interface, real components rather than a static image.

The output doesn't have to look generic either. AI can apply an existing design system so what comes back already looks like the product it's for, and some platforms carry that prompt all the way to a clickable prototype or frontend code.

Leading tools: Figma, Lovable, Bolt*

AI can generate code

Most engineering time goes to implementation, not decisions. AI can turn a spec or ticket straight into working code, generating the boilerplate and repetitive parts of a build so engineers spend their time on the harder ten percent.

That generation doesn't stop at a first draft either. AI can navigate an existing codebase, run the tests, and fix its own errors along the way, with some tools operating directly from the terminal to carry out multi-step changes with minimal hand-holding.

Leading tools: Claude Code, Copilot, Cursor*

AI can fix pipelines

A failed pipeline usually means someone stops what they're doing to dig through logs. AI can read those logs, identify what actually broke, and explain it in plain language before anyone opens a terminal.

Diagnosis is just the first step toward the fix, though. AI can propose the actual change needed, and some platforms open a merge request automatically the moment they've diagnosed a broken build.

Leading tools: GitHub Actions, GitLab CI*

Validate

AI can generate tests

Writing and maintaining test coverage is often the first thing to slip under deadline pressure. AI can generate functional, security, and performance tests directly from how the product actually behaves, rather than from a checklist someone has to keep updating by hand.

Those generated tests don't have to break every time the interface changes either. Some platforms self-heal automatically, adjusting the test to match new behavior instead of just failing and waiting for someone to notice.

Leading tools: Playwright, SonarQube, Mabl*

Do you need help transforming your business with AI and technology?

I can help.

I built a career creating software solutions that make complex processes simpler and faster. From product engineering to business transformation, I can lead your team to create solutions that lead to results.
